

Docker Container & Images

Docker Container:

Imagine you have a **toy box**. Inside the toy box, you keep your toys, batteries, and instructions all in one place.

A **Docker container** is like that toy box, but for software.

It packs your app, its tools, and everything it needs to run in one neat little box.

That way, no matter where you take the box (your computer, a friend's computer, a server in the cloud). It works the same, because the box already has everything inside.

In short: Docker container = Portable little box that can run your app anywhere.

Docker Image?

Think of a **Docker image** like a **recipe book**.

The recipe tells you exactly how to make a dish:

- Ingredients you need.
- The steps to cook it.

But you don't eat the recipe itself. You use it to make the actual food.

In the Docker world:

- **Image = recipe** (instructions + ingredients for your app).
- **Container = the actual dish** (the app running, made from the recipe).

So, you build containers **from** images, just like you **cook food** from a **recipe**.

Quick formula: Image = blueprint, Container = real thing.
