

Docker Image Layers & Port Binding

Image Layers:

Docker images are built in **layers**, kind of like a cake.

- Each instruction in a Dockerfile (FROM, RUN, COPY, etc.) makes a new layer.
- Layers are **stacked** to form the final image.
- Layers are **cached & shared** => so if two images use the same base, Docker doesn't store it twice.

```
FROM ubuntu:20.04    # base layer
RUN apt-get update    # new layer
COPY . ./app          # another layer
```

Layers = building blocks of an image that make it efficient and reusable.

Port Binding:

Port binding = Connecting a port on your computer (host) to a port inside the container.

```
docker run -p <host_port>:<container_port> image
docker run -p 8080:80 nginx
```

- 8080 = your computer's port
- 80 = port inside the container

Now we can open **http://localhost:8080** and reach Nginx running in the container.
